The screenshot displays a social media feed with three posts. Each post features a grid of hat images on the left and a text description on the right. The first post shows two black hats, one with a mesh back, priced at 3,89 C and 4,59 C. The second post shows two black hats, one with an Adidas logo, priced at 4,29 C and 13,90 C. The third post shows two black hats, one with a New Era logo, priced at 13,90 C and 13,90 C. The text descriptions are: 'Psychology Family time, couple time, and time alone with children contributes significantly to mothers' and fathers' well-being. Fathers enjoy family time more than mothers do. Unequal division of labour during family time explains this discrepancy.'; 'Earth Science A Tunguska sized airburst destroyed Tall el-Hammam a Middle Bronze Age city in the Jordan Valley near the Dead Sea.'; and 'Social Science People can distinguish dictators from democratic leaders based on their facial appearance alone'. Each post includes a title, price, and a link to the source.

Articles **Least squares support vector machine classifiers**
J.K. Suykens, J. Vandewalle - *Neural processing letters*, 1999 - Springer
Abstract In this letter we discuss a least squares version for **support vector machine (SVM)** classifiers. Due to equality type constraints in the formulation, the solution follows from solving a set of linear equations, instead of quadratic programming for classical SVM's. ...

Support vector machine classification and validation of cancer tissue samples using microarray expression data
T.S. Funtun, N. Cristofari, T. Duffy, D.W. Bednarski, ... - 2000 - Oxford Univ Press
Abstract Motivation: DNA microarray experiments generating thousands of gene expression measurements, are being used to gather information from tissue and cell samples regarding gene expression differences that will be useful in diagnosing disease. We have ...

Support vector machine active learning with applications to text classification
S. Tong, S. Koller - *Journal of machine learning research*, 2001 - jmlr.org
Abstract **Support vector** machines have met with significant success in numerous real-world learning tasks. However, like most **machine** learning algorithms, they are generally applied using a randomly selected training set classified in advance. In many settings, we also ...

R_n and $\frac{z_n}{n}$ converge, but to what limit?

Proposition (Market shares)

If $R_n \rightarrow r$, then $\frac{z_n(x)}{n} \rightarrow q(r; x)$ a.s.

Theorem (Possible limits)

For any $r \in \mathbb{R}$, we have $P(R_n \rightarrow r) > 0$ (for any initial condition) if and only if r contains no ties and it ranks the items by descending choice probability, that is

$$q(r^1(1); r) > q(r^1(2); r) > \dots > q(r^1(N); r)$$

Summary

References

- Search and satisficing [Simon, 1955], with search order induced by ranking:

$$q(a; r) = \frac{p_x^r (1 - p_x)^{r-1} p_a}{\sum_{y \in X} p_x^r (1 - p_x)^{r-1} p_y}$$

p_x : probability x accepted when searched.

SPC satisfied with $a \succ b$, $p_a > p_b$.

- Search and satisficing [Simon, 1955], with search order induced by ranking:

$$q(a; r) = \frac{P^x \cdot r^a \cdot Q}{P^y \cdot X \cdot x \cdot r \cdot y} \cdot \frac{(1 - p_x) \cdot p_a}{(1 - p_x) \cdot p_y};$$

p_x : probability x accepted when searched.

SPC satisfied with $a > b$, $p_a > p_b$.

- Multiplicative attention modulation (Germano et al., 2019):

$$q(a; r) = \frac{P^{r(a)} \cdot v_a}{P^{r(x)} \cdot v_x}$$

v_x : intrinsic quality of item x , $v_x \in (0; 1)$

SPC satisfied with $a > b$, $v_a > v_b$.

See also (Ciampaglia et al., 2018; Gaeta et al., 2022).

- Consideration sets model (Manzini & Mariotti, 2014; Masatlioglu, Nakajima, & Ozbay, 2012), with top- K ranked items in the consideration set, then use Luce rule:

$$q(a; r) = \sum_k P(K = k) \frac{v(a)}{\sum_{x:r(x) \leq k} v(x)} \mathbb{1}_{r(a) \leq k}$$

- Random utility model with additive ranking-dependent term (Pope, 2009):

$$q(a; r) = P \left(a = \arg \max_{x \in X} u(x; r) \right) ;$$

where

$$u(x; r) = v(x) + b(r(x)) + \epsilon(x)$$

b : decreasing function
 ϵ : random error term

- Herding model - Rational agents with unreliable private information (Banerjee, 1992).

Heterogeneous agents

Optimal ranking: $r^* = \arg \max_{r \in R} V(r)$

) R_n may in general converge to a suboptimal ranking

- A new theoretical framework for sequential choice systems and popularity dynamics
- Results about long-term behavior (possible outcomes, market shares), easy to check conditions
- Covers a wide variety of behavioral models
- Theory can cover other types of quantities with rich-get-richer dynamics (instead of popularity)
- Important caveat: It is restricted to ranking-based dynamics
